Introduction and Data

INSTRUCTIONS: This section includes an introduction to the project motivation, data, and research question. Describe the data and definitions of key variables. It should also include some exploratory data analysis. All of the EDA won't fit in the paper, so focus on the EDA for the response variable and a few other interesting variables and relationships.

Introduction

With the lifting of travel restrictions into the U.S. (<https://www.nytimes.com/2021/09/22/travel/us-international-travel-vaccine.html>) through the implementation of new travel guidelines, we believe that the booking of hotels may start to increase. Therefore, with the slower return to travel and society pre covid, we are interested in studying the characteristics of hotel room reservations in the United States. Specifically, we are interested in what relationship these characteristics have the cost of a hotel. Our general research question is; How do the characteristics of a hotel booking affect the daily cost of a hotel stay in the United States? We believe there will be several significant points of relevance for understanding these relationships: understanding predictors of room cost could be used to help identify where new hotels could be successfully created, allow travelers to plan financially for future travel.

In this report, we are looking to use linear models to understand the contributing factors to hotel room price, as well as identify the strongest predictors.

Data

The source of the dataset is Tiny Tuesday, <https://github.com/rfordatascience/tidytuesday/blob/master/data/2020/2020-02-11/readme.md>. This data set was originally collected from an open hotel booking demand dataset from Antonio, Almeida and Nunes, 2019. The data collected from hotels all around the world ranges from bookings in 2015 to 2017. It is sourced from this study <https://www.sciencedirect.com/science/article/pii/S2352340918315191#f0010>. Due to the dataset being over 100,000 observations, we have limited the observations to be only hotels from the US. The general characteristics being measured in the data are the different aspects of booking and staying at a hotel. For example, out of the 32 variables, some of the ones we find great interest in are hotel type, reserved room type, assigned room type, company, meal, number of adults/children/babies, the average daily rate or daily cost, and the reservation status. Therefore, each observation is one booking/stay at a specific hotel in America and all of its characteristics. Therefore, there can be multiple observations from the same hotel and even on the same time range. The full dataset dictionary can be found in the repository ReadMe.

Research Question

To better understand the contributing factors to the daily rate of hotel rooms in the U.S., we build a linear model to 1) evaluate the efficacy of this model to predict daily hotel room rates, and 2) evaluate the statistical significance of each predictor, identifying the strongest contributing factors. We include the following variables in our analysis: hotel type, reserved room type, assigned room type, company, meal, number of adults/children/babies, the average daily rate or daily cost, and the reservation status.

Exploratory data analysis

```
ggplot(data = hotels, aes(x = adr)) +  
  geom_histogram() +  
  labs(x = "Price in US Dollars",  
       y = "Frequency",  
       title = "Distribution of Average Daily Rate (Cost) of Hotel Bookings",  
       subtitle = "Collected from Hotels in the U.S. from 2015-2017")
```

```
## 'stat_bin()' using 'bins = 30'. Pick better value with 'binwidth'.
```

Distribution of Average Daily Rate (Cost) of Hotel Bookings

Collected from Hotels in the U.S. from 2015–2017

```
hotels %>%
  summarise(mean = mean(adr),
            median = median(adr),
            sd = sd(adr),
            min = min(adr),
            max = max(adr),
            iqr = IQR(adr))
```

```
## # A tibble: 1 x 6
##   mean median    sd  min  max  iqr
##   <dbl> <dbl> <dbl> <dbl> <dbl> <dbl>
## 1  123.   115  51.6    0  328.  62.0
```

The response variable, `adr`, has a somewhat skewed right, bimodal distribution. The average or mean average daily rate is \$122.992 and the median is \$115. Because the distribution is skewed, the median is most likely the best indicator for the center. The standard deviation is \$51.617 and the data ranges from \$0 to \$328.33 with an interquartile range of \$61.99.

```
sum(hotels$adults)
```

```
## [1] 3950
```

```
sum(hotels$children)
```

```
## [1] 362
```

```
sum(hotels$babies)
```

```
## [1] 6
```

We can see that most of the users were adults and not many users come with babies.

```
sum(hotels$meal == "BB")
```

```
## [1] 1563
```

```
sum(hotels$meal == "SC")
```

```
## [1] 478
```

```
sum(hotels$meal == "HB")
```

```
## [1] 55
```

We can see that most of the people use bed and breakfast plan rather than half board or full board.

Methodology

INSTRUCTIONS: This section includes a brief description of your modeling process. Explain the reasoning for the type of model you're fitting, predictor variables considered for the model including any interactions. Additionally, show how you arrived at the final model by describing the model selection process, any variable transformations (if needed), and any other relevant considerations that were part of the model fitting process.

Modeling Choices (Description)

- Data transformations (if applied)
- Model Type Justification
- Model selection criteria
- Handling Interaction Terms
- Any other technical choices

As of now, we know we are going to use hotel (Resort Hotel or City Hotel), reserved_room_type, assigned_room_type, company, customer_type, stays_in_weekend_nights, stays_in_week_nights, and meal(type of meal) as predictor variables. We are interested in how the food is served at a hotel and what type of hotel can indicate how much a night in a hotel could cost. As we explore more of the relationships in our dataset, we may add possible predictor variables as we see fit.

We plan to use multiple linear regression with a variety of combinations of interested predictor variables and their interaction. Based on whether conditions or fit or not or based on the visualization, we believe we may be utilizing logarithmic regression as well. We would also be interested in seeing how stays in the weekend or the weekday may affect the average daily rate for a hotel, and if they differ between the two hotel types, City and Resort hotels.

Modeling Code (Hide code with echo = False!)

Results

INSTRUCTIONS: In this section, you will output the final model and include a brief discussion of the model assumptions, diagnostics, and any relevant model fit statistics. This section also includes initial interpretations and conclusions drawn from the model.
